Motivation 1

Motivation

While working on ripping my Star Trek series collection it occurred that some seasons used a naming scheme of the resulting output files which were not in the proper order of the episodes.

So I did some research and stumbled across a makemkv forum entry which mentioned to make use of the internal mpls numbers to sort the episodes in the right order.

While that worked, finding those, put them in front of the file names, sorting and then renaming the resulting files properly this turned out to be a very time consuming and errorprone process.

Starting a little code test trying to parse the makemkvcon output was not so promising in lack of proper documentation. So I asked google's gemini for input and the result is documented within this project.

For a detailed technical specification see [usage](#)

For now there is only a JUnit test which reads the makemkvcon output, parses it and renames the output files in a given directory accordingly. After that one can rename the files using an episode guide.

As my Star Trek collection is now finally ripped completely this is sufficient enough for now. But there is more to come with my Star Gate collection ;) So idea is to create a modern UI utilizing Kotlin Multiplatform to replace the oldfashioned UI coming with makemkv as I do not believe there will be anything new anytime soon.
